(54) Title: A BINAURAL DIGITAL HEARING AID SYSTEM

## (57) Abstract

A binaural digital hearing aid system comprises two hearing aid units (1, 2) for arrangement in a user's left and right ear, respectively. Each unit comprises input signal transducer means (3r, 3l), A/D conversion means (4r, 4l), digital signal processing means (5r-13r, 5l-13l), D/A conversion means (14r, 14l) and output signal transducer means (15r, 15l). A bi-directional communication link (7) is provided between the units. The digital signal processing means of each unit is arranged to affect a substantially full digital signal processing including individual processing of signals from the input transducer means of the actual unit and simulated processing of signals from the input transducer means of the other unit as well as binaural signal processing and includes at least a first digital signal processor part (5r, 5l) for processing said internally supplied signal, a second digital signal processor part (6l, 6r) for processing the signal supplied via said communication link (7) and a third digital signal processor part (9r, 9l) to effect common binaural digital signal processing of information derived from the signals processed in said first and second digital signal processor parts, said second digital signal processor part (6l, 6r) in each unit simulating the first digital signal processor part (5l, 5r) in the other unit with respect to adjustment parameters controlling the performance of said first signal processor part in said other unit.

### A Binaural Digital Hearing Aid System

The invention relates to a binaural digital hearing aid system comprising two hearing aid units for arrangement in a user's left and right ear, respectively, each of said units comprising input signal transducer means for conversion of a received input sound signal into an analog input signal, A/D conversion means for conversion of said analog input signal into a digital input signal, digital signal processing means for processing said digital input signal and generating a digital output signal, D/A conversion means for conversion of said digital output signal into an analog output signal and output signal transducer means for conversion of said analog output signal into an output sound signal perceivable to the user, a bidirectional communication link being provided between said units to connect a point in the signal path between the input signal transducer means and the digital signal processing means in one of said units with a corresponding point in the signal path between the input signal transducer means and the digital signal processing means of the other of said units.

For normally hearing persons the ability to localize sounds in space defined as binaural hearing ability is an important part of the sound perception. Typically the amplitude of sound received by the ipsilateral ear which is closer to the source of sound, is of greater amplitude than the sound received by the opposite contralateral ear. This difference in sound level, although often small by itself, is of great importance for a human being's perception of the direction of an incident sound.

In the human hearing system binaural sound perception results from a complicated signal processing of sounds arriving at the left and right side ears, in

which time/phase and frequency distribution of the sound plays a decisive role. Thus, time/phase differences and frequency enhancement are important for determining directions in the horizontal and vertical  
5 planes, respectively.

With conventional analog hearing aids persons suffering from a binaural hearing impairment, i.e. a hearing loss affecting both ears, the customary practice has been to use two separate hearing aids adjusted  
10 to compensate individually for the hearing loss of the respective ear for which the hearing aid is operative and compensation of the loss of binaural sound perception, although typically made even worse by the very use of a hearing aid in both ears, has in most cases by  
15 and large been ignored.

As a relatively simple compensation, it has been suggested for each of the two hearing aids of an analog system to use a microphone with a pronounced direction dependent characteristic to provide an analog signal  
20 the level of which changes, when the hearing aid is moved from a position pointing towards the sound source to other position with a minimum level, when the hearing aid points in a direction at right angles to the direction to the sound source.

25 In US-A-3,509,289 a different concept for compensation of binaural hearing loss in an analog hearing aid system is disclosed involving the use of cross-coupled AGC circuitry for maintaining and enhancing the interaural level difference between contralateral  
30 and ipsilateral incident sound. In this system, the gain of each of a first and second amplifying channel is varied inversely with the output of the other channel by separate AGC circuits which are cross-coupled to stabilize the system.

35 With the introduction of digital signal processing

in hearing aids a significant improvement of hearing aid performance has become possible and more advanced proposals for binaural hearing loss compensation have seen the light.

5        Thus, US-A-5,479,522 discloses a hearing enhancement system comprising in addition to two hearing aid devices for arrangement in the left and right side ears, respectively, a body-worn pack comprising a remote digital signal processor connected to each of  
10 the hearing aid device by a down-link and an up-link for interactive digital processing of the audio signals for each ear based on signals received from both hearing aid devices. The common binaural digital signal processing is predetermined and limited to attenuation  
15 of noise and narrowing of the sound field or adapting the signal level in the two channels. The signals supplied to the common binaural signal processing are not affected by the individual hearing loss compensation in the two channels.

20        In addition, this prior art system reduces the comfort by requiring a separate body-worn signal processor in a addition to the two hearing aid devices and the physical links between the common binaural processor and the two hearing aid devices in the form of  
25 radio communications make the system susceptible to distortion affecting the quality of sound reproduction.

      In WO 97/14268, a binaural digital hearing aid system is disclosed in which the need for a separate body-worn remote control processor has been eliminated  
30 by the use of two hearing aid devices for arrangement in the left and right side ears, respectively, each of which incorporates a digital signal processor to which not only the unprocessed audio signal generated by the microphone in the same hearing aid device is supplied,  
35 but also the unprocessed audio signal generated by the

microphone in the opposite hearing aid device, the latter audio signal from each of the two devices being supplied to the respective opposite device through a bidirectional communication link.

5        This prior art system can be switched between distinct modes of either full binaural signal processing or performance as a conventional monaural hearing aid, which in one embodiment is done by giving the user the option of disabling the digital signal processor by  
10 either physically removing an external digital processing unit or by disabling a digital processor.

      In the binaural processing mode of this prior art system no account is taken of the difference with respect to hearing loss and compensation between the  
15 two ears and, somewhat generalized, the system could be seen as an advanced digital substitute for the above-mentioned relatively simple binaural compensation using microphones with a pronounced direction dependent characteristic.

20        On this background, it is the object of the invention to provide an improved digital binaural hearing aid system in which the above-mentioned shortcomings of prior art systems have been eliminated to provide for a binaural signal processing, which for persons with a  
25 binaural hearing loss will restore binaural sound perception while taking into account the difference in hearing loss and compensation between the two ears.

      According to the invention, a binaural digital hearing aid system as defined above is characterized in  
30 that the digital signal processing means of each unit is arranged to effect a substantially full digital signal processing including individual processing of signals from the input transducer means of the actual unit and simulated processing of signals from the input  
35 transducer means of the other unit as well as binaural

signal processing of signals supplied, on one hand, internally from the input signal transducer means of the same unit and, on the other hand, via said communication link from the input signal transducer means of the other unit, said digital signal processing means including at least a first digital signal processor part for processing said internally supplied signal, a second digital signal processor part for processing the signal supplied via said communication link and a third digital signal processor part to effect common binaural digital signal processing of information derived from the signals processed in said first and second digital signal processor parts, said second digital signal processor part in each unit simulating the first digital signal processor part in the other unit with respect to adjustment parameters controlling the performance of said first signal processor part in said other unit.

Thereby, in the binaural hearing aid system of the invention each of the hearing aid units for the left and right side ears, respectively, performs in addition to digital signal processing adapted to compensate for the hearing loss of the ear served by the unit, a simulated full digital signal processing of sound signals received by the unit for the opposite ear and adapted to compensate for the specific hearing loss of that ear, as well as a common binaural signal processing taking into account both of the normally different compensation characteristics of both units.

By the advantageous embodiments and modifications of the system set out in the dependant claims the system can be designed for user operated switching between functioning as a binaural system and a conventional monaural hearing system, and the digital signal processing means in each hearing unit may be

programmable to be switchable between different sound environments or listening situations by user operation, whereby programmed performance data for the first signal processing means of one unit is entered for  
5 programming of the second signal processing means of the other unit, in which the simulated signal processing of signals supplied from the first unit is carried out.

By the provision of only a single bidirectional communication link between the two hearing aid units,  
10 the hearing aid system of the invention is less susceptible to signal distortion and interruption than the prior art systems described above.

In the following the invention will be further explained with reference to the accompanying drawings  
15 on which

figure 1 is a schematic block diagram representation of an embodiment of the hearing aid system of the invention;

figure 2 a further detailed representation of the  
20 embodiment shown in figure 1; and

fig. 3 is a block diagram representation of one hearing aid unit of a programmable hearing aid system of the invention.

The binaural hearing system illustrated in figure  
25 1 comprises two hearing aid units 1 and 2 intended for arrangement in the user's right and left ears, respectively. The hearing aid units 1 and 2 are identical in structure, but as further explained in the following they will normally have been programmed or otherwise  
30 adjusted to provide different hearing loss compensation adapted to the specific hearing impairment of the ear, in which the unit is to be arranged. For the following description identical parts in the two units 1 and 2 will be designated by the same reference numeral  
35 followed by "r" and "l", respectively, to indicate the

localization of such parts in either the right ear or the left ear unit 1 or 2.

Each of units 1 and 2 comprises input signal transducer means e.g. in the form of one or more 5 hearing aid microphones 3r, 3l which receives sound signals to be processed in the unit and transforms these sound signals into analog electrical signals which are supplied to an A/D converter 4r, 4l for conversion into digital signals.

10 In the embodiment shown the digital signal from A/D converter 4r, 4l in each of units 1 and 2 is supplied to a first digital signal processor 5r, 5l which is programmed or otherwise adjusted to perform signal processing functions such as filtering, band- 15 division, amplification, gain control adjustment, compression, expansion and/or compensation for nonlinearities in the microphone or the user's ear channel.

However, to the extent that some of the signal processing functions of processors 5r, 5l may be 20 implemented in the A/D converters 4r, 4l, each of which will then supply a preprocessed digital signal, each of digital processors 5r, 5l need not be present as a separate unit.

According to the invention, each of units 1 and 2 25 also comprises a second digital signal processor 6l and 6r, respectively, which is structurally identical to processor 5r, 5l, but is programmed or otherwise adjusted to perform digital signal processing functions on the signals received by the opposite ear, i.e. 30 processor 6l in unit 1 for the right ear is programmed to provide the specific signal processing intended for the left ear and will thus, in principle, provide the same signal processing as signal processor 5l in unit 2, whereas signal processor 6r in unit 2 will provide 35 the same signal processing as processor 5r in unit 1.

In the embodiment shown the digital electrical signal from converter 4r, 4l in each of units 1 and 2 is additionally supplied via a communication link 7 to second signal processor 6r, 6l in the other unit, such that in each unit the second signal processor 6l, 6r performs a simulated processing corresponding to the processing by first signal processor 5l, 5r in the other unit. However, as an alternative the analog signals from microphone 3r, 3l in each of units 1 and 2 could be communicated directly and supplied to A/D conversion in the other unit.

The signal processors 5r, 5l and 6r, 6l will typically be state of the art digital hearing aid processors programmed to perform a relatively sophisticated signal processing with respect to sound/noise separation and user operated adaptability to a number of different sound environments or listening situations.

The communication link 7 between the right and left hearing aid units 1 and 2 is preferably a single bidirectional communication link which may be physically implemented by a cable extending between the two units. the hearing aid units 1 and 2 may be designed for arrangement in the ear (ITE) or behind the ear (BTE). In either case a cable connection between the units may extend around the neck of the user and may eventually be integrated in a necklace or similar piece of jewelry or bijouterie.

Alternatively, the bidirectional communication link 7 may be wireless and, as shown in dashed lines, comprise antennas 7r, 7l connected with appropriate transceiving means 8r, 8l in each unit. For hearing units in ITE design such an antenna may be physically implemented by a relatively short piece of wire or string which in use will project outside the ear and

may serve additionally to facilitate withdrawal of the hearing unit from its ITE position.

In each of units 1 and 2 the first and second digital signal processors 5r, 5l and 6l, 6r outputs a  
5 processed digital signal which is supplied to a third signal processor 9r, 9l which, in accordance with the invention performs a common binaural digital signal processing of the processed digital signals outputted from the first and second signal processors 5r, 5l and  
10 6l, 6r.

The binaural signal processing in each of third signal processors 9r, 9l may make use of state of the art binaural processing techniques taking into account differences with respect to amplitude, phase-lag etc.  
15 between arrival of incoming sounds at the input transducers of the right and left ear hearing aid units. As result of this binaural signal processing which according to the invention is based on information derived from the processed digital signals in both of units 1  
20 and 2, the third signal processor 9l, 9r in each unit outputs processed digital right and left binaural signal parts which in digital adder devices 10r, 10l and 11l, 11r is combined with the processed digital output signal from first signal processor 5r, 5l in the  
25 same unit.

In each unit the combined processed digital signals from adder device 10r, 10l may be supplied directly to a D/A converter 14r, 14l for conversion into a processed analog signal which is supplied to an  
30 output transducer device in the form of a conventional hearing aid telephone 15r, 15l. As illustrated the processed digital signals from adder devices 10r, 10l and 11r, 11l may optionally undergo a further digital signal processing in fourth signal processors 12r, 12l  
35 and fifth signal processors 13r, 13l, respectively,

which may include compensation of the specific hearing loss and automatic gain control. From processors 12r, 12l and 13r, 13l feedback signals are also supplied to the binaural processor 9r, 9l.

5       The processing functions of the fourth and fifth signal processors 12r, 12l and 13r, 13l in each of units 1 and 2 may be implemented in the binaural processor 9r, 9l so that processors 12r, 12l and 13r, 13l may in principle be dispensed with as separate  
10 units. The binaural signal processor 9r, 9l may then further be designed to output only the binaural digital signal part intended for the actual unit, i.e, the right ear binaural signal part for unit 1 and the left ear binaural signal part for unit 2. In both cases, the  
15 incorporation of the fourth and fifth signal processors either as separate units or in the binaural processor 9r, 9l provides an advantageous possibility, however, for an AGC function and/or hearing loss compensation in the binaural signal processor 9r, 9l by feed-back of  
20 the processed digital output signals from both of the fourth and fifth signal processors 12r, 12l and 13r, 13l to the binaural processor 9r, 9l.

Examples of digital signal processors for use in each of units 1 and 2 are disclosed e.g. in EP-B1-0 732  
25 036, US-A-5,165,017, US-A-4,531,229 and US-A-5,144,675. An advanced signal processing method and device employing so-called dynamic AGC has been disclosed in copending international patent application PCT/DK97/00598, the disclosure of which is incorporated  
30 herein by reference.

The design and structure of the binaural hearing system of the invention, by which all information carrying signals in the separate signal channels for the right ear and the left ear sound perception are  
35 made available for processing in both of units 1 and 2

not only of the signal actually belonging to the respective side, but also, by simulated processing, of the signal belonging to the other side, opens the possibility of implementing complex and highly sophisticated binaural signal processing to restore binaural hearing ability without significant complication of the structure. In fact, both of hearing aid units 1 and 2 may be identical in structure and equipped with identical components like converters, signal processors etc.

10       Whereas the various signal processors in each of units 1 and 2 have been illustrated and described as separate processors they may advantageously be incorporated as separate processing parts of a common single digital processor such as a microprocessor.

15       The embodiment of the hearing aid system shown in figure 2 serves to illustrate the degree of complexity of binaural signal processing that can be implemented in each of the right and left ear hearing aid units 16 and 17 with a single bidirectional communication link

20 28 between the two units.

Using the same distinction as to reference numerals between the right and left ear units as used for the embodiment in figure 1 only the structure and function of the right ear unit 16 will be explained in

25 the following.

The unprocessed analog signal from microphone 18r is preamplified and converted to digital form in preamplifier and A/D converter 19r and processed to compensate for nonlinearity of the microphone and the

30 sound perception in the ear in linearity control unit 20r, from which a preprocessed digital signal is supplied, on one hand to a band divider filtering unit 21r in the signal processing channel for the right ear and, on the other hand, via the bidirectional communication link 28 to a band divider filtering unit 21rs in

35

**THIS PAGE BLANK (USPTO)**

the processing part of the left ear unit 17 performing the simulated right ear signal processing.

In the band divider filtering unit 21r the incoming preprocessed digital signal is split into a number of frequency bands, each of which is further processed in a noise filtering unit 22r and a processing unit 23r in which the signal is amplified in accordance with the compensation characteristic adapted to compensate for the specific hearing loss of the right ear.

10 As for the embodiment in figure 1 each of the two hearing aids comprise in addition to the signal processing channel for the ear in which the unit is arranged a separate signal processing channel effecting a simulated signal processing corresponding to the  
15 signal processing in the other unit. In the embodiment in figure 2 this simulated processing channel comprises for the right ear hearing aid unit 16 processing units 21ls, 22ls and 23ls effecting the same processing functions as processing units 21r, 22r and 23r for the  
20 right ear compensation, but adjusted to the specific characteristics for the left ear compensation effected in the left ear hearing aid unit 17.

The left ear hearing aid unit 17 is identical in structure to the right ear hearing aid unit 16 and  
25 comprises the left ear signal processing channel with processing unit 19l and 20l and filtering and compensation units 21l, 22l and 23 l as well as the simulated right ear processing channel including units 21rs, 22rs and 23rs.

30 In each of hearing aid units 16 and 17 binaural signal processing may be effected in two processing units 24, 24l and 25r, 25l. Thus, in the right ear hearing aid unit 16 a first binaural processing unit 24r may receive the band divided output signals from  
35 filtering unit 21r in the right ear processing channel

as well as from filtering unit 21ls in the simulated left ear processing channel and provide correction signals affecting signal scaling in processing units 22r and 22ls and a second binaural processing unit 25r  
5 may effect further binaural signal processing on incoming signal from the first binaural processing unit 24r as well as from processing units 22r, 22ls and 23r, 23ls.

Finally, in each of hearing aid units 16 and 17  
10 the output signal from processing unit 23r, 23l in the right and left ear processing channel, respectively, and the binaural output signal from the second binaural processing unit 25r. 25l is reconverted into analog form in an output processing unit 26r, 26l and supplied  
15 to an output transducer such as a conventional hearing aid telephone 27r, 27l.

In each of hearing aid units 16 and 17 all of processing units 22 to 25 may be designed for automatic gain control (AGC), e.g. as disclosed in the above-  
20 mentioned copending international patent application PCT/DK97/000598.

In each of hearing aid units 16 and 17 the processing units 21 to 25 are thus interconnected via a multiplicity of internal information and control  
25 signals lines, whereas the only external connection to the other hearing aid unit is via the single directional communication link 28.

According to a particular aspect of the invention the signal lines connecting the processing units 21 to  
30 23 of the right and left ear processing channels and the simulated left and right ear processing channels to the binaural processing units 24 and 25 may be opened and closed or activated and deactivated by control of appropriate switching means, not illustrated, whereby  
35 an advantageous adjustment flexibility is obtained with

a smooth transition ranging from full binaural signal processing approximating the sound information processing of the human brain via a more simple binaural sound level control to conventional monaural sound reproduction, contrary to the separation of the processing units for normal and binaural processing in the prior art system of WO 97/14268 explained above.

The signals supplied in each of the right and left ear hearing aid units to the binaural signal processing in units 24 and 25 may as illustrated in figure 2 be microphone signals which have been preprocessed by conversion into digital form and correction of frequency and/or level distortions caused by nonlinearities in the microphone circuits and/or following from the arrangement in the user's ear channel. Preferably, the incoming signals for the binaural processing have been filtered to the desired frequency band width.

Moreover as shown in figure 2 the preprocessed microphone signal supplied from each of hearing aid units 16 and 17 to the simulated processing channel of the other unit may be limited, e.g. by compression in an additional compressor unit 28r, 28l, to reduce the dynamic range, the band width and/or the number of samplings, thereby reducing the amount of data or information to be processed by the simulated processing. A similar signal limitation may also be provided, e.g. by an additional compressor unit 29r, 29l for the signals supplied in each hearing unit from the signal processing channel for the right or left ear, respectively, to binaural signal processing. In either case the processing units, to which such compressed signals are supplied, must be designed for processing these signals.

The binaural signal processing effected by processing units 24 and 25 may comprise a level correc-

tion, by which the gain in the hearing aid unit, right or left, receiving the weakest incoming sound signal is controlled on the basis of the incoming sound signal at the other hearing aid unit as represented, e.g. by the  
5 preprocessed microphone signal communicated therefrom via communication link 28 for simulated signal processing. Thereby, the sound level ratio between sounds received by the right and left ears, respectively. and the spatial information provided thereby may be main-  
10 tained also for hearing aid units with automatic gain control (AGC), sin AGC control can be effected on the basis of the strongest processed signal in the right or left ear units 16 and 17

The complexity allowed for the internal signal  
15 processing in each of hearing aid units 16 and 17 would also allow a compensation for time delays introduced e.g. by the signal communication via communication link 28, if necessary.

For hearing aids which as shown in figure 2  
20 employs sound or signal processing in a number of separate frequency bands with automatic gain control in each band the processing complexity and/or capacity further entails a data or information transfer between the real and simulated processing channels in each unit  
25 to provide for equal adaptation of the gain control of these processing channels, whereby the overall transfer function of each hearing aid unit may be adapted to take account of sound spectrum differences occurring at the right and left sides, thereby taking account of the  
30 frequency distribution in the spectra of sounds received at the right and left ears, which is very important for the localization of a sound source in space.

Since, in each of the right and left ear hearing  
35 aid units 16 and 17 in figure 2 all processing units

19r - 23r, 19l - 23l for the actual right or left ear signal processing channel and all processing units 21ls - 23ls, 21rs - 23rs for the simulated signal processing channel are programmed or otherwise adjusted to the  
5 specific processing parameters for the right and left ear signal processing, respectively, or vice versa, the binaural signal processing in each side takes fully account of the specific hearing loss characteristics of both sides up to or even beyond the output signal  
10 transducer 26r and 26l, respectively.

To accomplish this the binaural signal processing effected in the right and left ear hearing units 16 and 17 will typically be mirror images of each other to restore the actual sound level and sound spectrum  
15 differences between incoming sounds at the right and left ears, respectively.

As a special advantage of the binaural signal processing in each of the two hearing units of the system according to the invention a sophisticated noise  
20 or feedback suppression is made possible, by which tone signals deviating from the overall sound image may be effectively suppressed without suppression of tone signals present in the overall sound signal or in the right and left side at the same time. This can be  
25 accomplished by including in the binaural sound processing unit a feedback suppression system to which a residual feedback signal representing the difference feedback signals from the actual and simulated sound processing channels is supplied. By means of such a  
30 feedback suppression it is possible for the hearing aid system of the invention to distinguish between howl and information sound signals of a similar character such as a tone from a flute solo in classical music composition or alarm or signalling tones such as  
35 walk/stop beeps at traffic lights.

In each of hearing aid units 16 and 17 the performance of each of signal processing units 21r - 23r, 21l - 23l in the real signal processing channel as well as the performance of each of the processing units 21ls 5 - 23ls, 21rs - 23rs in the simulated processing channel is controlled by adjustment parameters or data adapted to the specific compensation requirements of the right and left ears, respectively.

According to the invention such adjustment parameters may be individually programmable to compensate for the user's specific hearing impairment with respect to the right and left ears, whereby the hearing aid system may be supplied with a standard adjustment to permit individual programming to be effected by a hearing aid 15 fitter as is customary practice in the individual user adjustment of hearing aids.

Moreover, the adjustment parameters may be organized in different programme settings to permit operation of the hearing aid system in different modes 20 ranging from fully binaural to simple monaural operation of the hearing aid units and/or permit adaption of the hearing aid system to varying sound environments or listening situations.

Figure 3 shows for one of the hearing aid units in 25 the system illustrated in figure 2, i.e. the right ear hearing aid unit 16 how this is accomplished by means of a performance and programme memory 30 in which all programmable adjustment parameters for a number of specific performance programmes are entered and may be 30 selected from a selection unit 31 which may be user operated and/or operated from a sound signal analyzer 32 to effect programme selection automatically in response to occurrence of specified sound signal conditions.

35      Optionally, at least one of hearing aid units 16

or 17 may include means for calculation of intermediate settings between at least two consecutive performance programme settings, in which case also such intermediate settings will be selectable from the selection unit  
5 31.

Since as a result of the structure and organization of hearing aid units 16 and 17 to effect not only the actual signal processing for the ear in which the unit is arranged, but also the simulated processing for  
10 the opposite ear memory 30 will contain all adjustment parameters needed for the signal processing for both sides, the programming of the hearing aid system may be effected by entering of adjustment parameters and user operated or automatically activated performance pro-  
15 grammes in memory 30 of the one of hearing aid units 16 and 17 only and effecting transfer of adjustment parameters for the processing units of the other hearing aid unit via the communication link 28 in an adjustment or initiation mode activated at each change  
20 of performance programme.

Ultimately this makes possible to operate the system according to the invention by a master-slave principle, in which case one of the hearing aid units would function as a master unit and take control of the  
25 other unit functioning as a slave unit in which memory 30 would then contain the information or parameters needed for the actual function of the slave unit.

Alternatively, various kinds of intermediate or mixed organization schemes could be foreseen, e.g. by  
30 designing both hearing units with user operated as well as automatic programme selection. This could provide e.g. for consensus operation in situations where one unit would try to shift automatically to a specific programme matching prevailing sound signal conditions,  
35 by effecting an exchange of actual adjustment parameter

settings between the two units via communication link 28 to enable a decision to be made in one of the units as to whether the programme selected by one of the units should be effected for both units.

5        In each of the two units synchronization means 33 may further be provided for the exchange of synchronization information between the signal processing parts of the two units via the communication link 28. Such synchronizing information may be derived from the  
10 signals otherwise transferred between the two units or be generated as separate synchronizing signals.

      User operability may advantageously be effected by wireless remote control from a separate control unit carried by the user. This is suitable, in particular,  
15 for embodiments in which wireless transmission is already used for the bidirectional communication link between the two hearing aid units.

## P A T E N T   C L A I M S

1. A binaural digital hearing aid system comprising two hearing aid units for arrangement in a user's left and right ear, respectively, each of said units  
5 comprising input signal transducer means for conversion of a received input sound signal into an analog input signal, A/D conversion means for conversion of said analog input signal into a digital input signal, digital signal processing means for processing said  
10 digital input signal and generating a digital output signal, D/A conversion means for conversion of said digital output signal into an analog output signal and output signal transducer means for conversion of said analog output signal into an output sound signal  
15 perceivable to the user, a bidirectional communication link being provided between said units to connect a point in the signal path between the input signal transducer means and the digital signal processing means in one of said units with a corresponding point  
20 in the signal path between the input signal transducer means and the digital signal processing means of the other of said units, c h a r a c t e r i z e d in that the digital signal processing means of each unit (1, 2; 16, 17) is arranged to effect a substantially full  
25 digital signal processing including individual processing of signals from the input transducer means (3r, 3l; 18r, 18l) of the actual unit and simulated processing of signals from the input transducer means of the other unit as well as binaural signal processing of signals  
30 supplied, on one hand, internally from the input signal transducer means of the same unit and, on the other hand, via said communication link (7; 28) from the input signal transducer means of the other unit, said digital signal processing means including at least a  
35 first digital signal processor part (5r, 5l, 12r, 12l;

21r-23r, 21l-23l) for processing said internally supplied signal, a second digital signal processor part (6l, 6r, 13l, 13r; 21ls-23ls, 21rs-23rs) for processing the signal supplied via said communication link (28) and a third digital signal processor part (9r, 9l; 24r-25r, 24l-25l) to effect common binaural digital signal processing of information derived from the signals processed in said first and second digital signal processor parts, said second digital signal processor part (6l, 6r, 13l, 13r; 21ls-23ls, 21rs-23rs) in each unit simulating the first digital signal processor part (5l, 5r, 12l, 12r; 21l-23l, 21r-23r) in the other unit with respect to adjustment parameters controlling the performance of said first signal processor part in said other unit.

2. A hearing aid system as claimed in claim 1, characterized in that said bidirectional communication link (7) is a wireless transmission link, transceiving means (8r, 8l) and antenna means (7r, 7l) being provided in each of said hearing aid units.

3. A hearing aid system as claimed in claim 2, characterized in that said antenna means (7r, 7l) in each hearing unit comprises a short piece of antenna wire projecting externally from an ear mold arranged in ITE or CIC position and acting simultaneously as a withdrawal string.

4. A hearing aid system as claimed in claim 1, 2 or 3, characterized in that in at least one of said hearing aid units (16, 17) adjustment parameters for processing units in an actual signal processing channel effecting signal processing adapted to the ear in which the unit is arranged as well as further adjustment parameters for the simulated signal processing channel effecting said simulated signal processing adapted to the ear in which the other unit

is arranged are entered into a memory (30).

5. A hearing aid system as claimed in claim 4, characterized in that said memory (30) further includes performance programme settings to provide varying operation modes ranging from fully binaural signal processing to simple monaural signal processing in the hearing aid units and/or provide adaption of system performance to different sound environments or listening situations.

10 6. A hearing aid system as claimed in claim 5, characterized in that at least one of said hearing aid units (1, 2; 16, 17) include means for calculation of intermediate settings between at least two consecutive performance programme settings.

15 7. A hearing aid system as claimed in claim 5 or 6, characterized in that programme selection means (31) for said performance programme settings including said intermediate settings are user operated and/or automatically activated on the basis of incoming sound signal analysis.

8. A hearing aid system as claimed in any of claims 2 or 3 and claim 7, characterized in that said selection means (31) are remotely controlled by wireless transmission of control signals.

25 9. A hearing aid system as claimed in any of claims 5 to 8, characterized in that said memory (30) is provided in one hearing aid unit only acting as a master unit, said bidirectional communication link (28) being designed for transfer of adjustment parameter settings from said one unit to the other unit acting as a slave unit.

10. A hearing aid system as claimed in any of claims 6, 7 or 8, characterized in that each of said hearing aid units (16, 17) is provided with said memory (30) and said programme selection

35

means (31), said selection means (31) being designed in both units for user operation as well as automatic activation, said bidirectional communication link (28) being designed for exchange of parameter settings between the two units and one of the units including decision means to provide for a consensus control of the system.

11. A hearing aid system as claimed in any of the preceding claims, characterized in that the binaural signal processing functions in each of the two hearing aid units are mirrored with respect to the binaural signal processing functions in the other unit to take account of sound level and/or sound spectrum differences between incoming sound signal at the right and left ear hearing aid units.

12. A hearing aid system as claimed in claim 11, characterized in that the binaural signal processing part of each of said hearing aid units comprises a feedback howl suppression system providing howl suppression by processing of a residual signal representing the difference between feedback signals in the actual and simulated signal processing channels.

13. A hearing aid system as claimed in any of any of the preceding claims, characterized in that in each of the hearing aid units means are provided for limitation, e.g. by compression of the signals supplied from said first and second processor parts to said third processor part.

14. A hearing aid system as claimed in any of the preceding claims, characterized in that means (33) are provided in each of the two hearing aid units for exchange of synchronization information between the signal processing parts of the two units.

# INTERNATIONAL SEARCH REPORT

In International Application No  
PCT/DK 98/00062

## A. CLASSIFICATION OF SUBJECT MATTER

IPC 6 H04R25/00

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)  
IPC 6 H04R

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	WO 97 14268 A (AUDIOLOGIC INC) 17 April 1997 cited in the application see page 3, line 5 - line 25 see page 4, line 29 - page 7, line 6; figures ---	1
A	US 5 511 128 A (LINDEMANN) 23 April 1996 see column 2, line 35 - column 4, line 19; figures ---	1
A	US 5 479 522 A (LINDEMANN ET AL.) 26 December 1995 cited in the application see column 2, line 11 - line 59 see column 3, line 50 - column 6, line 20 --- -/--	1

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

### \* Special categories of cited documents :

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

- "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
- "&" document member of the same patent family

Date of the actual completion of the international search
